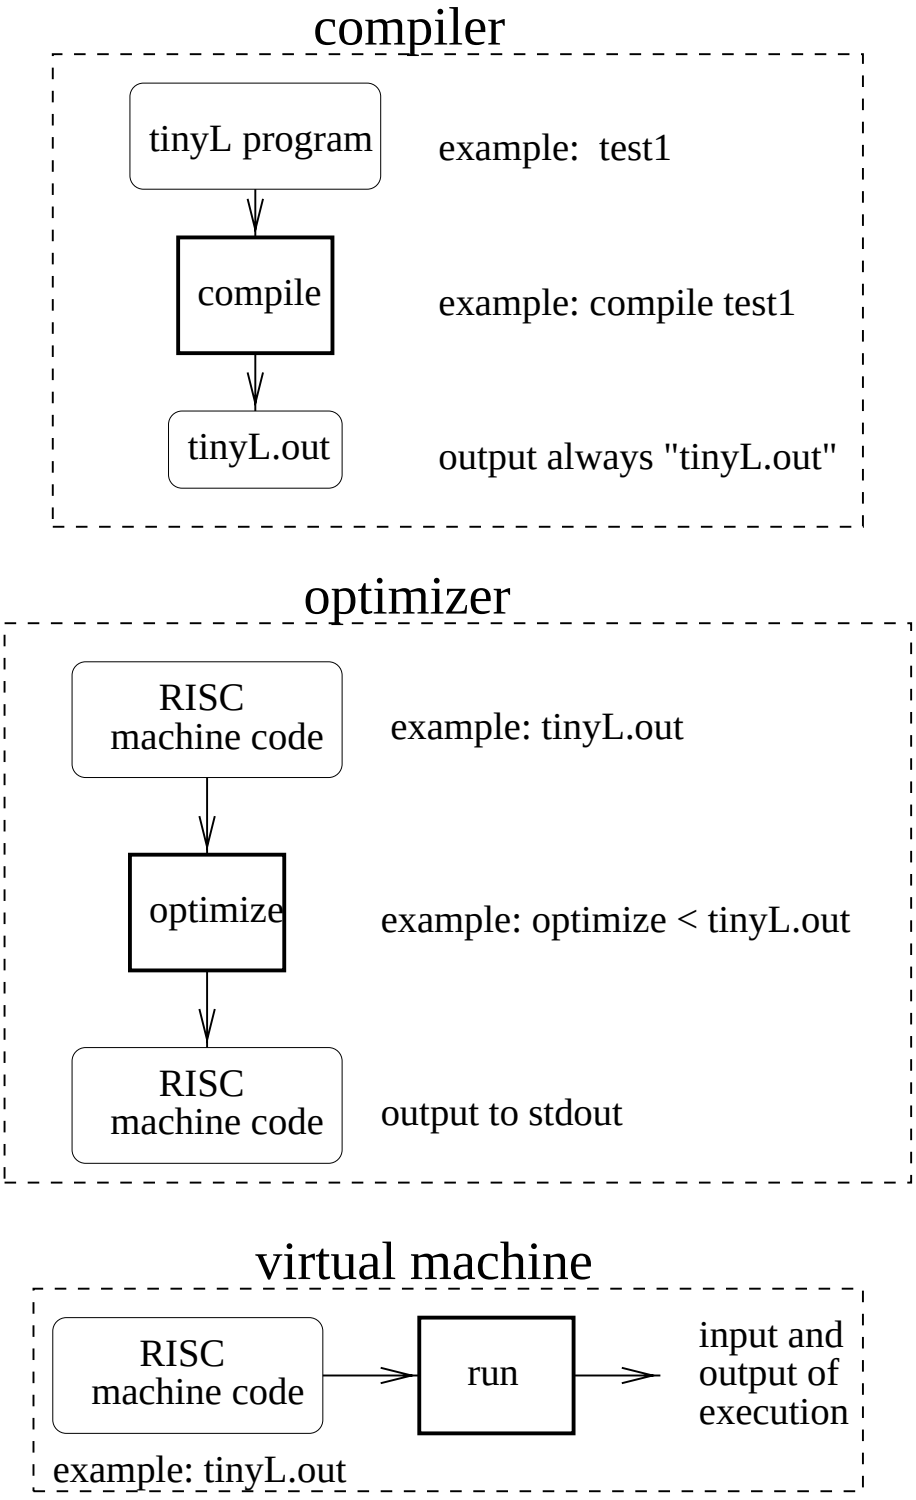
Class Information

- First project has been posted.
- Fourth homework will be posted by tonight.

Project 1: Overview



Project 1: Dead Code Elimination

Goal: Identify instructions that do not contribute to the input/output behavior of the program.

These instructions are considered "dead" and can be eliminated.

Example:

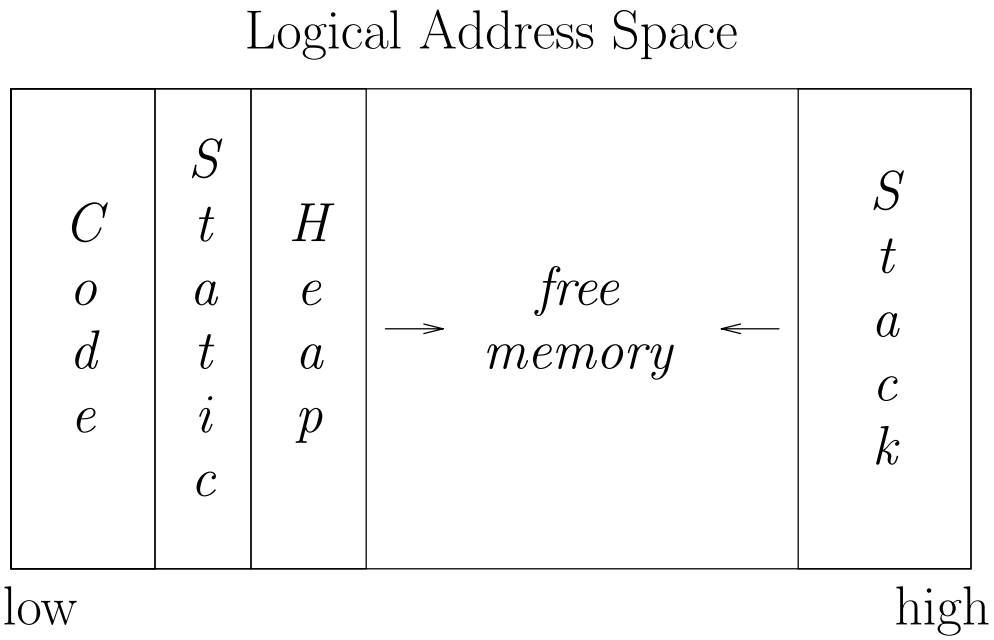
```
LOADI r1 5
LOADI r2 7
LOADI r3 2
ADD r4 r1 r2
MUL r5 r1 r2
STORE a r5
WRITE a
```

Code after 'dead" instructions have been eliminated:

```
LOADI r1 5
LOADI r2 7
MUL r5 r1 r2
STORE a r5
WRITE a
```

Review: Run-time storage organization

Typical memory layout



The classical scheme

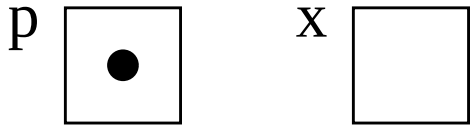
- allows both stack and heap maximal freedom
- code and static may be separate or intermingled

Review: Pointers in C

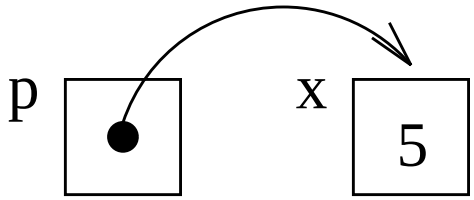
Pointer: Variable whose R-values (content) is the L-value (address) of a variable

- "address-of" operator &
- dereference ("content-of") operator $*$

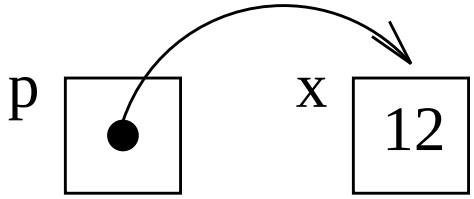
```
int *p, x;
```



```
p = &x;
*p = 5;
```



```
x = 12;
```



Lecture 9 Example: Singly-linked list

```
int main (void)
{
  int j;

  /* CREATE FIRST LIST ELEMENT */
  head = (listcell *) malloc(sizeof(listcell));
  head->num = 1;
  head->next = NULL;

  /* CREATE 9 MORE ELEMENTS */
  for (j=2; j<=10; j++) {
    new_cell = (listcell *) malloc(sizeof(listcell));
    new_cell->num = j;
    new_cell->next = head;
    head = new_cell;
  }

  /* PRINT ALL ELEMENTS */
  for (current_cell = head;
       current_cell != NULL;
       current_cell = current_cell->next)
    printf("%d ", current_cell->num);

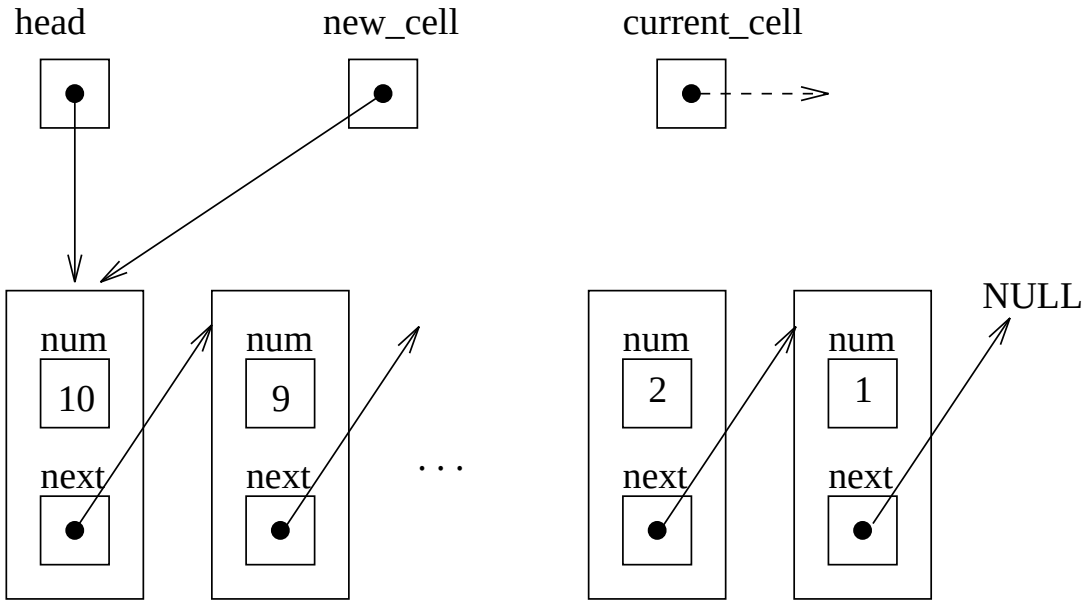
  printf("\n");
}
```

Lecture 9 Example: Singly-linked list

```
int main (void)
{
  int j;

  /* CREATE FIRST LIST ELEMENT */
  head = (listcell *) malloc(sizeof(listcell));
  head->num = 1;
  head->next = NULL;

  /* CREATE 9 MORE ELEMENTS */
  for (j=2; j<=10; j++) {
    new_cell = (listcell *) malloc(sizeof(listcell));
    new_cell->num = j;
    new_cell->next = head;
    head = new_cell;
  }
     /* *** HERE *** */
```



Review: Stack vs. Heap

Stack:

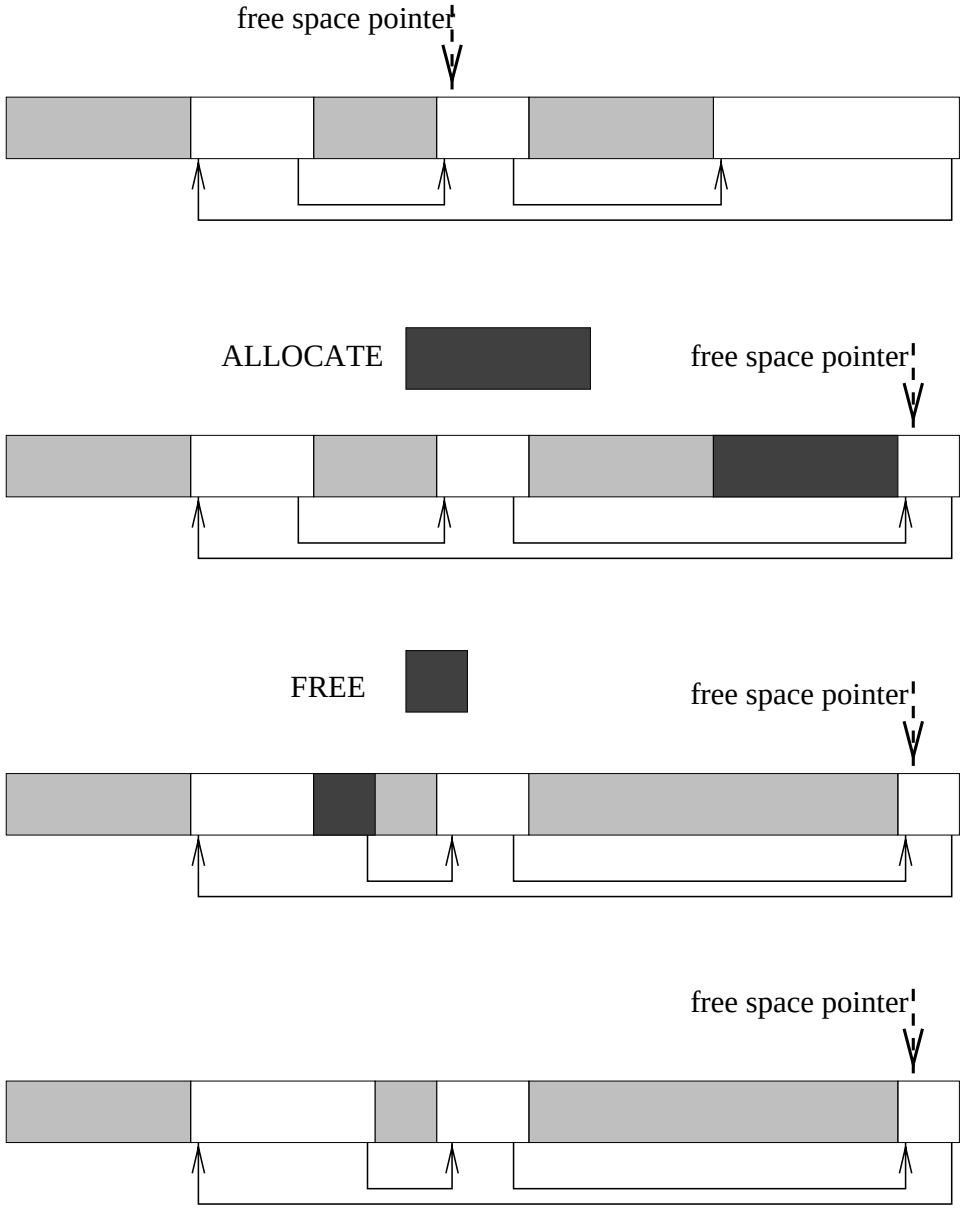
- Procedure activations, statically allocated local variables, parameter values
- Lifetime same as subroutine in which variables are declared
- Stack frame is pushed with each invocation of a subroutine, and poped after subroutine exit

Heap:

- Dynamically allocated data structures, whose size may not be known in advance
- Lifetime extends beyond subroutine in which they are created
- Must be explicitly freed or garbage collected

Maintaining Free List

- **allocate**: continous block of memory; remove space from free list (here: singly-linked list).
- **free**: return to free list after coalescing with adjacent free storage (if possible); may initiate compaction.



Heap Storage

`void * malloc(size_t n)` (defined in stdlib.h)

- returns pointer to block of contiguous storage of `n` bytes on the heap, if possible
- returns NULL pointer if not enough memory is available
  ⇒ you should check for `==NULL` after each malloc
  NOTE: we didn't do this in the example!
- to allocate storage of a desired type, call `malloc` with the needed size in bytes, and then cast the return pointer to the desired type
  head = (listcell *) malloc(sizeof(listcell));

`void free(void *ptr)` (defined in stdlib.h)

- data structure that `ptr` points to is released, i.e., returned to the free memory and may be (partially) reused by a subsequent `malloc`.

Problems with Explicit Control of Heap

- **Dangling references**
  - Storage pointed to is freed, but pointer (or reference) is not set to NULL
  - Able to access storage whose values are not meaningful
- **Garbage**
  - Objects in heap that cannot be accessed by the program any more
  - Example

```
int *x, *y;
x = (int *) malloc(sizeof(int));
y = (int *) malloc(sizeof(int));
x = y;
```

- **Memory leaks**
  - Failure to release (reclaim) memory storage builds up over time

Example: Singly-linked list

Let's deallocate, i.e., free all list elements.

```
#include "list.h"
/* GLOBAL VARIABLES */
  listcell *head, *new_cell, *current_cell;
int main (void) {
  int j;

  /* CREATE FIRST LIST ELEMENT */
 . . .

  /* CREATE 9 MORE ELEMENTS */
 . . .

  /* DEALLOCATE LIST */
  for (current_cell = head;
       current_cell != NULL;
       current_cell = current_cell->next)
    free(current_cell);
  }
 . . .
}
```

Does this work?

What went wrong?

Uninitialized variables and "dangerous" casting

```
#include <stdio.h>
#include <stdlib.h>
int main(void)
{
  int *a;

  *a = 12;
  printf("%x %x: %d\n", &a, a, *a);

  a = (int *) 12;
  printf("%d\n", *a);
}
```

> a.out
effff60c effff68c: 12
Segmentation fault (core dumped)

Note: Segmentation faults result in the generation of a core file which can be rather large. Don't forget to delete it.

What went wrong?

That's better!

```
#include <stdio.h>
#include <stdlib.h>
int main(void)
{
  int *a = NULL; /* good practice */

  a = (int *) malloc(sizeof(int));
  *a = 12;
  printf("%x %x: %d\n", &a, a, *a);
}
```

> a.out

effff60c 20900: 12

What went wrong?

The machine or compiler must be broken!?!!

```
#include <stdio.h>
#include <stdlib.h>

int main (void)
{
  int i;

  char *string = "Hello, how     are   you   today.";
  printf("\n%s\n", string);

  for (i=0; string[i] != '.'; i++) {
    if (string[i] = ' ')
      for (; string[i] = ' ';i++);
    printf("%c", string[i]);
  }
  printf(".\n");
}
```

> a.out

Hello, how are you today.

Segmentation fault (core dumped)

What went wrong?

"=" is not the same as "=="

```
#include <stdio.h>
#include <stdlib.h>

int main (void)
{
  int i;

  char *string = "Hello, how     are   you   today.";
  printf("\n%s\n", string);

  for (i=0; string[i] != '.'; i++) {
    if (string[i] == ' ')
      for (; string[i] == ' ';i++);
    printf("%c", string[i]);
  }
  printf(".\n");
}
```

> a.out

Hello, how are you today.

Hello,howareyoutoday.

What went wrong?

"Aliasing" and freeing memory

```
#include <stdio.h>
#include <stdlib.h>
int main(void)
{
  int *a = NULL; int *b = NULL; int *c = NULL;

  a = (int *) malloc(sizeof(int));
  b = a; *a = 12;
  printf("%x %x: %d\n", &a, a, *a);
  printf("%x %x: %d\n", &b, b, *b);
  free(a);
  printf("%x %x: %d\n", &b, b, *b);

  c = (int *) malloc(sizeof(int));
  *c = 10;
  printf("%x %x: %d\n", &c, c, *c);
  printf("%x %x: %d\n", &b, b, *b);
}
```

> a.out
