

CS314 Spring 2014

Assignment 6

Due Friday, April 4, **before** class

Problem 1 – Parameter Passing

```
program foo()
{
    a, b integer;
    procedure bar(integer x, integer y)
    {
        z: integer;

        <----- /* 0 */
        z = 5;                /* 1 */
        x = x + y + z;        /* 2 */
        y = 1;                /* 3 */
    }
    // statement body of foo
    a = 1;
    b = 2;
    call bar(a, b);
    print a, b; }
}
```

Use the RISC machine instructions `LOAD`, `STORE`, `LOADI`, `ADD` as used in the non-local data access example (lecture 13, pages 11 and 12) to show the code that needs to be generated for the body of procedure `bar` (statements `/*1*/` through `/*3*/`). Assume that

1. Register `r0` contains the frame pointer (`fp`) value.
2. Formal parameter `x` is **call-by-reference**, and formal parameter `y` is **call-by-value**. Assume that `bar`'s parameters `x` and `y` have been correctly initialized as part of the procedure call of `bar`.
3. Use the stack frame layout as shown above. The figure shows the runtime stack when the program execution reaches program point `/*0*/` in procedure `bar`.

What values for `a` and `b` does the program print?

Problem 2 – Parameter Passing

Assume that you don't know what particular parameter passing style a programming language is using. In order to find out, you are asked to write a short test program that will print a different output depending on whether a *call-by-value*, *call-by-reference*, or *call-by-value-result* parameter passing style is used. Your test program must have the following form:

```
program main()
{
    a integer;
    procedure foo(integer x)
    {
        // statement body of foo
    }

    // statement body of main
    a = 1;
    call foo(a);
    print a;
}
```

The body of procedure *foo* must only contain assignment statements. For instance, you are not allowed to add any new variable declarations.

1. Write the body of procedure *foo* such that **print a** in the **main** program will print different values for the different parameter passing styles.
2. Give the output of your test program and explain why your solution works.

Problem 3 – Scheme

Write Scheme programs that generate the following lists as output using only `cons` as the list building operator:

1. `'(a b (c d (e f (g))))`
2. `'((((a) b c) d) (e f)) g)`
3. `'(a + 3)` such that `((cadr '(a + 3)) 3 5)` evaluates to 8.

Problem 4 – Scheme

Write the following functions on lists in Scheme. The semantics of the functions is described through examples.

1.

```
(define flatten
  (lambda (l)
    ... ))
...
(flatten '(a ((b) (c d) (((e)))))) --> '(a b c d e)
```
2.

```
(define rev
  (lambda (l)
    ... ))
...
(rev '(a((b)(c d)(((e)))))) --> '((((e))(d c)(b))a)
```

Note: Do not use the Scheme build-in function "reverse".

3.

```
(define double
  (lambda (l)
    ... ))
...
(double '(a((b)(c d)(((e)))))) --> '(a a((b b)(c c d d)(((e e)))))
```
4.

```
(define delete
  (lambda (atom l)
    ... ))
...
(delete 'c '(a((b)(c d)(((e)))))) --> '(a((b)(d)(((e))))))
(delete 'f '(a((b)(c d)(((e)))))) --> '(a((b)(c d)(((e))))))
```
